

Sorting Algorithms

Sorting is the process of arranging the elements of an array so that they can be placed either in ascending or descending order. For example, consider an array $A = \{A_1, A_2, A_3, A_4, \dots, A_n\}$, the array is called to be in ascending order if element of A are arranged like $A_1 < A_2 < A_3 < A_4 < A_5 < \dots < A_n$.

Consider an array;

`int A [10] = {5, 4, 10, 2, 30, 45, 34, 14, 18, 9 }`

The Array sorted in ascending order will be given as;

`A [] = {2, 4, 5, 9, 10, 14, 18, 30, 34, 45}`

There are many techniques by using which, sorting can be performed. In this section of the tutorial, we will discuss each method in detail.

Sorting Algorithms

Sorting algorithms are described in the following table along with the description.

SN	Sorting Algorithms	Description
1	Bubble Sort	It is the simplest sort method which performs sorting by repeatedly moving the largest element to the highest index of the array. It comprises of comparing each element to its adjacent element and replace them accordingly.
2	Insertion Sort	As the name suggests, insertion sort inserts each element of the array to its proper place. It is a very simple sort method which is used to arrange the deck of cards while playing bridge.
3	Selection Sort	Selection sort finds the smallest element in the array and place it on the first place on the list, then it finds the second smallest element in the array and place it on the second place. This process continues until all the elements are moved to their correct ordering. It carries running time $O(n^2)$ which is worst than insertion sort.

Bubble sort Algorithm

In this article, we will discuss the Bubble sort Algorithm. The working procedure of bubble sort is simplest. This article will be very helpful and interesting to students as they might face bubble sort as a question in their examinations. So, it is important to discuss the topic.

Bubble sort works on the repeatedly swapping of adjacent elements until they are not in the intended order. It is called bubble sort because the movement of array elements is just like the movement of air bubbles in the water. Bubbles in water rise up to the surface; similarly, the array elements in bubble sort move to the end in each iteration.

Although it is simple to use, it is primarily used as an educational tool because the performance of bubble sort is poor in the real world. It is not suitable for large data sets. The average and worst-case complexity of Bubble sort is $O(n^2)$, where n is a number of items.

Bubble sort is majorly used where –

- complexity does not matter
- simple and shortcode is preferred

Algorithm

In the algorithm given below, suppose **arr** is an array of **n** elements. The assumed **swap** function in the algorithm will swap the values of given array elements.

1. begin BubbleSort(arr)
2. for all array elements
3. if $arr[i] > arr[i+1]$
4. swap($arr[i]$, $arr[i+1]$)
5. end if
6. end for
7. return arr
8. end BubbleSort

Working of Bubble sort Algorithm

Now, let's see the working of Bubble sort Algorithm.

To understand the working of bubble sort algorithm, let's take an unsorted array. We are taking a short and accurate array, as we know the complexity of bubble sort is $O(n^2)$.

Let the elements of array are -

13	32	26	35	10
----	----	----	----	----

First Pass

Sorting will start from the initial two elements. Let compare them to check which is greater.

13	32	26	35	10
----	----	----	----	----

Here, 32 is greater than 13 ($32 > 13$), so it is already sorted. Now, compare 32 with 26.

13	32	26	35	10
----	----	----	----	----

Here, 26 is smaller than 36. So, swapping is required. After swapping new array will look like -

13	26	32	35	10
----	----	----	----	----

Now, compare 32 and 35.

13	26	32	35	10
----	----	----	----	----

Here, 35 is greater than 32. So, there is no swapping required as they are already sorted.

Now, the comparison will be in between 35 and 10.

13	26	32	35	10
----	----	----	----	----

Here, 10 is smaller than 35 that are not sorted. So, swapping is required. Now, we reach at the end of the array. After first pass, the array will be -

13	26	32	10	35
----	----	----	----	----

Now, move to the second iteration.

Second Pass

The same process will be followed for second iteration.

13	26	32	10	35
----	----	----	----	----

13	26	32	10	35
----	----	----	----	----

13	26	32	10	35
----	----	----	----	----

Here, 10 is smaller than 32. So, swapping is required. After swapping, the array will be -

13	26	10	32	35
----	----	----	----	----

13	26	10	32	35
----	----	----	----	----

Now, move to the third iteration.

Third Pass

The same process will be followed for third iteration.

13	26	10	32	35
----	----	----	----	----

13	26	10	32	35
----	----	----	----	----

Here, 10 is smaller than 26. So, swapping is required. After swapping, the array will be -

13	10	26	32	35
----	----	----	----	----

13	10	26	32	35
----	----	----	----	----

13	10	26	32	35
----	----	----	----	----

Now, move to the fourth iteration.

Fourth pass

Similarly, after the fourth iteration, the array will be -

10	13	26	32	35
----	----	----	----	----

Hence, there is no swapping required, so the array is completely sorted.

```
#include<stdio.h>
int main(){
    int a[50], i,j,n,t;
    printf("enter the No: of elements in the list:");
    scanf("%d", &n);
    printf("enter the elements:");
    for(i=0; i<n; i++){
        scanf ("%d", &a[i]);
    }
    printf("Before bubble sorting the elements are:");
    for(i=0; i<n; i++)
        printf("%d \t", a[i]);
    for (i=0; i<n-1; i++){
        for (j=i+1; j<n; j++){
            if (a[i] > a[j]){
                t = a[i];
                a[i] = a[j];
                a[j] = t;
            }
        }
    }
    printf ("after bubble sorting the elements are:");
    for (i=0; i<n; i++)
        printf("%d\t", a[i]);
    return 0;
}
```

Output

When the above program is executed, it produces the following result –

```
enter the No: of elements in the list:
5
enter the elements:
12 11 45 26 67
Before bubble sorting the elements are:
12
11
45
```

26
67
after bubble sorting the elements are:
11 12 26 45 67

Bubble sort complexity

Now, let's see the time complexity of bubble sort in the best case, average case, and worst case. We will also see the space complexity of bubble sort.

1. Time Complexity

Case	Time Complexity
Best Case	$O(n)$
Average Case	$O(n^2)$
Worst Case	$O(n^2)$

- **Best Case Complexity** - It occurs when there is no sorting required, i.e. the array is already sorted. The best-case time complexity of bubble sort is **$O(n)$** .
- **Average Case Complexity** - It occurs when the array elements are in jumbled order that is not properly ascending and not properly descending. The average case time complexity of bubble sort is **$O(n^2)$** .
- **Worst Case Complexity** - It occurs when the array elements are required to be sorted in reverse order. That means suppose you have to sort the array elements in ascending order, but its elements are in descending order. The worst-case time complexity of bubble sort is **$O(n^2)$** .

2. Space Complexity

Space Complexity	$O(1)$
Stable	YES

- The space complexity of bubble sort is $O(1)$. It is because, in bubble sort, an extra variable is required for swapping.
- The space complexity of optimized bubble sort is $O(2)$. It is because two extra variables are required in optimized bubble sort.

Insertion Sort Algorithm

In this article, we will discuss the Insertion sort Algorithm. The working procedure of insertion sort is also simple. This article will be very helpful and interesting to students as they might face insertion sort as a question in their examinations. So, it is important to discuss the topic.

Insertion sort works similar to the sorting of playing cards in hands. It is assumed that the first card is already sorted in the card game, and then we select an unsorted card. If the selected unsorted card is greater than the first card, it will be placed at the right side; otherwise, it will be placed at the left side. Similarly, all unsorted cards are taken and put in their exact place.

The same approach is applied in insertion sort. The idea behind the insertion sort is that first take one element, iterate it through the sorted array. Although it is simple to use, it is not appropriate for large data sets as the time complexity of insertion sort in the average case and worst case is $O(n^2)$, where n is the number of items. Insertion sort is less efficient than the other sorting algorithms like heap sort, quick sort, merge sort, etc.

Insertion sort has various advantages such as -

- Simple implementation
- Efficient for small data sets
- Adaptive, i.e., it is appropriate for data sets that are already substantially sorted.

Now, let's see the algorithm of insertion sort.

Algorithm

The simple steps of achieving the insertion sort are listed as follows -

Step 1 - If the element is the first element, assume that it is already sorted. Return 1.

Step2 - Pick the next element, and store it separately in a **key**.

Step3 - Now, compare the **key** with all elements in the sorted array.

Step 4 - If the element in the sorted array is smaller than the current element, then move to the next element. Else, shift greater elements in the array towards the right.

Step 5 - Insert the value.

Step 6 - Repeat until the array is sorted.

Working of Insertion sort Algorithm

Now, let's see the working of the insertion sort Algorithm.

To understand the working of the insertion sort algorithm, let's take an unsorted array. It will be easier to understand the insertion sort via an example.

Let the elements of array are -

12	31	25	8	32	17
----	----	----	---	----	----

Initially, the first two elements are compared in insertion sort.

12	31	25	8	32	17
----	----	----	---	----	----

Here, 31 is greater than 12. That means both elements are already in ascending order. So, for now, 12 is stored in a sorted sub-array.

12	31	25	8	32	17
----	----	----	---	----	----

Now, move to the next two elements and compare them.

12	31	25	8	32	17
----	----	----	---	----	----

12	31	25	8	32	17
----	----	----	---	----	----

Here, 25 is smaller than 31. So, 31 is not at correct position. Now, swap 31 with 25. Along with swapping, insertion sort will also check it with all elements in the sorted array.

For now, the sorted array has only one element, i.e. 12. So, 25 is greater than 12. Hence, the sorted array remains sorted after swapping.

12	25	31	8	32	17
----	----	----	---	----	----

Now, two elements in the sorted array are 12 and 25. Move forward to the next elements that are 31 and 8.

12	25	31	8	32	17
----	----	----	---	----	----

12	25	31	8	32	17
----	----	----	---	----	----

Both 31 and 8 are not sorted. So, swap them.

12	25	8	31	32	17
----	----	---	----	----	----

After swapping, elements 25 and 8 are unsorted.

12	25	8	31	32	17
----	----	---	----	----	----

So, swap them.

12	8	25	31	32	17
----	---	----	----	----	----

Now, elements 12 and 8 are unsorted.

12	8	25	31	32	17
----	---	----	----	----	----

So, swap them too.

8	12	25	31	32	17
---	----	----	----	----	----

Now, the sorted array has three items that are 8, 12 and 25. Move to the next items that are 31 and 32.

8	12	25	31	32	17
---	----	----	----	----	----

Hence, they are already sorted. Now, the sorted array includes 8, 12, 25 and 31.

8	12	25	31	32	17
---	----	----	----	----	----

Move to the next elements that are 32 and 17.

8	12	25	31	32	17
---	----	----	----	----	----

17 is smaller than 32. So, swap them.

8	12	25	31	17	32
---	----	----	----	----	----

8	12	25	31	17	32
---	----	----	----	----	----

Swapping makes 31 and 17 unsorted. So, swap them too.

8	12	25	17	31	32
---	----	----	----	----	----

8	12	25	17	31	32
---	----	----	----	----	----

Now, swapping makes 25 and 17 unsorted. So, perform swapping again.

8	12	17	25	31	32
---	----	----	----	----	----

Now, the array is completely sorted.

Implementation of insertion sort

```
1. #include <stdio.h>
2.
3. void insert(int a[], int n) /* function to sort an array with insertion sort */
4. {
5.     int i, j, temp;
6.     for (i = 1; i < n; i++) {
7.         temp = a[i];
8.         j = i - 1;
9.
10.        while(j >= 0 && temp <= a[j]) /* Move the elements greater than temp to one position
    ahead from their current position */
11.        {
12.            a[j+1] = a[j];
13.            j = j-1;
14.        }
15.        a[j+1] = temp;
16.    }
17. }
18.
19. void printArr(int a[], int n) /* function to print the array */
```

```

20. {
21.   int i;
22.   for (i = 0; i < n; i++)
23.     printf("%d ", a[i]);
24. }
25.
26. int main()
27. {
28.   int a[] = { 12, 31, 25, 8, 32, 17 };
29.   int n = sizeof(a) / sizeof(a[0]);
30.   printf("Before sorting array elements are - \n");
31.   printArr(a, n);
32.   insert(a, n);
33.   printf("\nAfter sorting array elements are - \n");
34.   printArr(a, n);
35.
36.   return 0;
37. }

```

Output:

```

Before sorting array elements are -
12 31 25 8 32 17
After sorting array elements are -
8 12 17 25 31 32

```

Insertion sort complexity

Now, let's see the time complexity of insertion sort in best case, average case, and in worst case. We will also see the space complexity of insertion sort.

1. Time Complexity

Case	Time Complexity
Best Case	$O(n)$
Average Case	$O(n^2)$
Worst Case	$O(n^2)$

- **Best Case Complexity** - It occurs when there is no sorting required, i.e. the array is already sorted. The best-case time complexity of insertion sort is **$O(n)$** .
- **Average Case Complexity** - It occurs when the array elements are in jumbled order that is not properly ascending and not properly descending. The average case time complexity of insertion sort is **$O(n^2)$** .
- **Worst Case Complexity** - It occurs when the array elements are required to be sorted in reverse order. That means suppose you have to sort the array elements in ascending order, but its elements are in descending order. The worst-case time complexity of insertion sort is **$O(n^2)$** .

2. Space Complexity

Space Complexity	$O(1)$
Stable	YES

- The space complexity of insertion sort is $O(1)$. It is because, in insertion sort, an extra variable is required for swapping.

Selection Sort Algorithm

In this article, we will discuss the Selection sort Algorithm. The working procedure of selection sort is also simple. This article will be very helpful and interesting to students as they might face selection sort as a question in their examinations. So, it is important to discuss the topic.

In selection sort, the smallest value among the unsorted elements of the array is selected in every pass and inserted to its appropriate position into the array. It is also the simplest algorithm. It is an in-place comparison sorting algorithm. In this algorithm, the array is divided into two parts, first is sorted part, and another one is the unsorted part. Initially, the sorted part of the array is empty, and unsorted part is the given array. Sorted part is placed at the left, while the unsorted part is placed at the right.

In selection sort, the first smallest element is selected from the unsorted array and placed at the first position. After that second smallest element is selected and placed in the second position. The process continues until the array is entirely sorted.

The average and worst-case complexity of selection sort is **$O(n^2)$** , where **n** is the number of items. Due to this, it is not suitable for large data sets.

Selection sort is generally used when -

- A small array is to be sorted
- Swapping cost doesn't matter
- It is compulsory to check all elements

Now, let's see the algorithm of selection sort.

Algorithm

1. SELECTION SORT(arr, n)
- 2.
3. Step 1: Repeat Steps 2 and 3 for i = 0 to n-1
4. Step 2: CALL SMALLEST(arr, i, n, pos)
5. Step 3: SWAP arr[i] with arr[pos]
6. [END OF LOOP]
7. Step 4: EXIT
- 8.
9. SMALLEST (arr, i, n, pos)
10. Step 1: [INITIALIZE] SET SMALL = arr[i]
11. Step 2: [INITIALIZE] SET pos = i
12. Step 3: Repeat for j = i+1 to n
13. if (SMALL > arr[j])
14. SET SMALL = arr[j]
15. SET pos = j
16. [END OF if]
17. [END OF LOOP]
18. Step 4: RETURN pos

Working of Selection sort Algorithm

Now, let's see the working of the Selection sort Algorithm.

To understand the working of the Selection sort algorithm, let's take an unsorted array. It will be easier to understand the Selection sort via an example.

Let the elements of array are -

12	29	25	8	32	17	40
----	----	----	---	----	----	----

Now, for the first position in the sorted array, the entire array is to be scanned sequentially.

At present, **12** is stored at the first position, after searching the entire array, it is found that **8** is the smallest value.

12	29	25	8	32	17	40
----	----	----	---	----	----	----

So, swap 12 with 8. After the first iteration, 8 will appear at the first position in the sorted array.

8	29	25	12	32	17	40
---	----	----	----	----	----	----

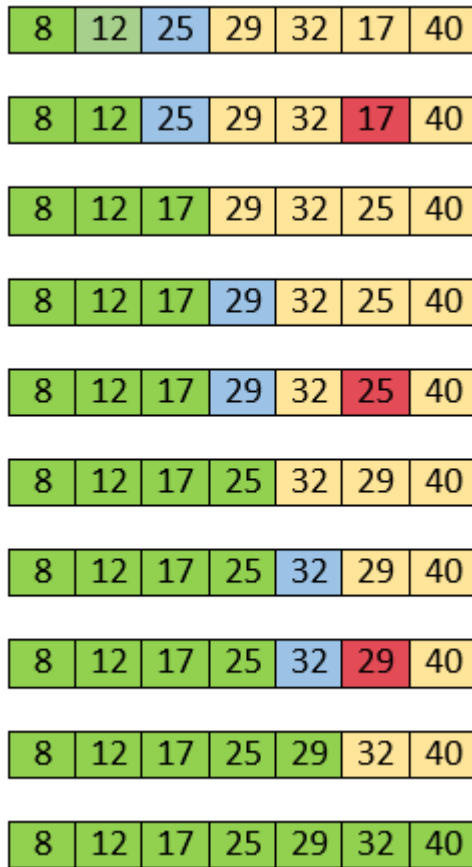

For the second position, where 29 is stored presently, we again sequentially scan the rest of the items of unsorted array. After scanning, we find that 12 is the second lowest element in the array that should be appeared at second position.

8	29	25	12	32	17	40
---	----	----	----	----	----	----

Now, swap 29 with 12. After the second iteration, 12 will appear at the second position in the sorted array. So, after two iterations, the two smallest values are placed at the beginning in a sorted way.

8	12	25	29	32	17	40
---	----	----	----	----	----	----

The same process is applied to the rest of the array elements. Now, we are showing a pictorial representation of the entire sorting process.

Now, the array is completely sorted.

Selection sort complexity

Now, let's see the time complexity of selection sort in best case, average case, and in worst case. We will also see the space complexity of the selection sort.

1. Time Complexity

Case	Time Complexity
Best Case	$O(n^2)$
Average Case	$O(n^2)$
Worst Case	$O(n^2)$

- **Best Case Complexity** - It occurs when there is no sorting required, i.e. the array is already sorted. The best-case time complexity of selection sort is **$O(n^2)$** .

- **Average Case Complexity** - It occurs when the array elements are in jumbled order that is not properly ascending and not properly descending. The average case time complexity of selection sort is $O(n^2)$.
- **Worst Case Complexity** - It occurs when the array elements are required to be sorted in reverse order. That means suppose you have to sort the array elements in ascending order, but its elements are in descending order. The worst-case time complexity of selection sort is $O(n^2)$.

2. Space Complexity

Space Complexity	$O(1)$
Stable	YES

- The space complexity of selection sort is $O(1)$. It is because, in selection sort, an extra variable is required for swapping.

Implementation of selection sort

```

1. #include <stdio.h>
2.
3. void selection(int arr[], int n)
4. {
5.     int i, j, small;
6.
7.     for (i = 0; i < n-1; i++) // One by one move boundary of unsorted subarray
8.     {
9.         small = i; //minimum element in unsorted array
10.
11.         for (j = i+1; j < n; j++)
12.             if (arr[j] < arr[small])
13.                 small = j;
14. // Swap the minimum element with the first element
15.     int temp = arr[small];
16.     arr[small] = arr[i];
17.     arr[i] = temp;
18. }
19. }
20.
21. void printArr(int a[], int n) /* function to print the array */
22. {
23.     int i;
24.     for (i = 0; i < n; i++)
25.         printf("%d ", a[i]);
26. }
```

```
27.  
28. int main()  
29. {  
30.     int a[] = { 12, 31, 25, 8, 32, 17 };  
31.     int n = sizeof(a) / sizeof(a[0]);  
32.     printf("Before sorting array elements are - \n");  
33.     printArr(a, n);  
34.     selection(a, n);  
35.     printf("\nAfter sorting array elements are - \n");  
36.     printArr(a, n);  
37.     return 0;  
38. }
```

Output:

After the execution of above code, the output will be -

```
Before sorting array elements are -  
12 31 25 8 32 17  
After sorting array elements are -  
8 12 17 25 31 32
```
